Busbars are continuously connected in parallel

Overview

Busbars are metallic strips, often made of copper or aluminum, that distribute power in high-current DC systems. When configured in parallel topologies, busbars can handle large currents efficiently while minimizing power losses and reducing thermal issues. Consequently, power busing design needs critical consideration in terms of performance under converter operation, asymmetric loading, short-circuits, thermal and insulation breakdown. They are used where a circuit needs a compact, reliable, high-current connection point, such as switchgear, panelboards, substations, busway, battery systems, and. As part of my research, I'm doing calculations on a hypothetical high-current (4000 A) medium-voltage (5000 V) DC power transmission system using two parallel busbars. However, I need to decide how the busbars are oriented relative to each other, and I can't find information on what best practices. Busbars simplify high-current distribution, reduce clutter, and can improve reliability if sized correctly. Busbar design is still resistance/heat engineering: thickness, width, material, and mounting affect performance. Plan for continuous current + surge; hotspots often occur at studs and. In order to improve the current capacity of the converters, IGBT multi-module parallel connection has been widely used due to its economy.
