DAC fiber optic patch cord components

Overview

A Direct Attach Cable (DAC) is a fixed-length assembly with pluggable transceiver modules already attached at each end — no separate optics, no fiber patch cord, no light source required.

Key Takeaways

DAC fiber optic patch cords are composed of a copper or fiber core, connectors, protective jacket, and strength members, designed for short-distance, high-speed connections in data centers.

Core Components of DA

C Fiber Optic Patch Cords

Conductive Core / Optical Fiber: For DAC (Direct Attach Copper) cables, the core consists of copper twinaxial wires that carry electrical signals directly between devices without the need for optical transceivers ( ). For fiber-based DAC or hybrid assemblies, the core is glass or plastic optical fiber, which transmits light signals for high-speed data transfer ( ). Connectors: DAC cables are terminated with SFP+, SFP28, QSFP+, QSFP28, QSFP-DD, or OSFP connectors, which plug directly into network devices like switches, servers, or storage units ( ).

Fiber DA

Cs may use LC, SC, MPO/MTP, or hybrid connectors depending on the application ( ). Connector ferrules can have different polish types: PC, UPC, or APC, affecting return loss and signal reflection ( ). Protective Jacket: The outer layer is typically PVC, LSZH, OFNR, or OFNP, providing mechanical protection, fire resistance, and environmental durability ( ).

The jacket also maintains cable integrity and protects internal components from bending, abrasion, and environmental stress. Strength Members: Aramid yarn (Kevlar®) is commonly used to provide tensile strength, preventing the cable from breaking during installation or handling ( ). In copper DACs, the strength members also help maintain connector alignment and prevent stress on the twinaxial wires.

Buffer Coating (for fiber DACs): Optical fibers are coated with a buffer layer to protect the glass core from mechanical damage, temperature variations, and chemical exposure ( ). The buffer also facilitates connectorization and splicing.

Additional Features

Simplex vs Duplex: DAC cables can be single-pair (simplex) or dual-pair (duplex) for bidirectional communication ( ). Active vs Passive DAC: Active DACs include signal-boosting electronics in the connectors to extend reach and improve signal integrity, while passive DACs rely solely on the electrical signal from the device ( ). Breakout and Hybrid Assemblies: Some DACs split one high-speed port into multiple lower-speed channels or combine copper and fiber in hybrid assemblies for flexible deployment ( ).

SummaryDAC fiber optic patch cords integrate core conductors or fibers, connectors, protective jackets, and strength members into a compact, factory-terminated assembly. They are optimized for short-distance, high-speed connections in data centers, offering low latency, cost efficiency, and plug-and-play simplicity.

Fiber-based DA

Cs combine optical fibers with standard connectors and buffer coatings, while copper DACs use twinaxial wires with optional active electronics for signal enhancement ( ).
