Fiber optic cable laying traction force

Overview

For fiber optic cable, the tensile strength of a cable represents the highest load or pulling force that can be placed upon any cable before any damage occurs to the fibers or their optical properties and characteristics. This is not the cable breaking strength, but a realistic allowable limit. Manufacturers specify this value, and it varies significantly based on cable design. For example, a heavy-duty armored outside plant cable handles much higher tension than a delicate. Minimize mechanical pressure on the outer sheath at crossing points: (armoured) cables crossing each other generate points of high pressure, so it is important when laying in figure 8 loops it is done in a correct way. When laying loops of fiber on a surface during a pull, use “figure-8” loops to. Tensile strength measures the maximum pulling force a fiber optic cable can withstand before breaking.
