Fiber optic multimode fusion splicing modes

Overview

Another technique is fusion splicing, where the fibers are fused together, e.g. using an electrical arc. This leads to particularly low insertion loss and high return loss, if the two fiber cores are similar.

Key Takeaways

Multimode fusion splicing mode is a specialized setting on fusion splicers optimized for joining multimode fibers, accounting for their larger core size and graded-index structure.

Overview of Fusion Splicing

Fusion splicing is the process of permanently joining two optical fibers by melting their ends together using an electric arc, creating a low-loss, strong, and reliable connection. It is the preferred method for both single-mode and multimode fibers because it minimizes insertion loss and reflection compared to mechanical splicing. The quality of the splice depends heavily on precise fiber cleaving and alignment before fusing.

Multimode Fiber Characteristics

Multimode fibers (MM) have a larger core diameter than single-mode fibers, typically 50 or 62. 5 microns, and a graded-index profile that allows multiple light modes to propagate simultaneously. This structure makes multimode fibers more sensitive to misalignment and core mismatches during splicing, which can increase splice loss if not properly managed.

Multimode Fusion Splicing Mode

Multimode (MM) splice mode on a fusion splicer is specifically designed to handle the unique properties of multimode fibers. Key features include: Arc Power Adjustment: The splicer automatically sets the arc intensity and duration to accommodate the larger core and multiple glass layers of multimode fibers. Core Alignment: MM mode ensures proper alignment of the fiber cores to reduce insertion loss and prevent light from coupling into cladding modes.

Optimized Parameters: The splicer may adjust heating time and fusion parameters differently than single-mode mode to account for the graded-index profile and larger core diameter.

Applications

Local Area Networks (LANs) and data centers where multimode fibers are commonly used. Short- to medium-distance optical links where multimode fibers provide cost-effective high-bandwidth transmission. Bulk installations where speed and consistency are important, as MM mode automates parameter selection for reliable splices.

Comparison with Other ModesSingle-Mode (SM) Mode: Optimized for small-core fibers with low dispersion; requires precise alignment and lower arc power. Manual Mode: Allows full control over arc intensity, splice time, and alignment, useful for experimental setups or non-standard fibers. Auto Mode: Detects fiber type automatically and selects appropriate parameters, suitable for beginners or high-volume splicing.

Using the multimode fusion splicing mode ensures that the splice is optimized for multimode fiber characteristics, minimizing loss and maximizing signal quality in optical networks.
